

Proposed Solution

Project: **Auto Ticket Classification using Flow Design**

Proposed Solution Template

S.No.	Parameter	Description
1	Problem Statement (Problem to be solved)	Support teams classify and route tickets manually, which is slow, inconsistent and delays urgent issues.
2	Idea / Solution Description	An automated flow that cleans ticket text, predicts category and priority using an ML classifier, and routes tickets through decision nodes. Low-confidence tickets go to a human review queue.
3	Novelty / Uniqueness	Combines a visual decision flow with ML classification, confidence-based fallback to humans, and a feedback loop where agent corrections improve the model.
4	Social Impact / Customer Satisfaction	Faster responses, fewer bounced tickets, urgent cases handled first, and less stress for support staff.
5	Business Model (Revenue Model)	SaaS subscription per agent or per ticket volume; add-on integration and analytics packages.
6	Scalability of the Solution	Modular services (flow engine, classifier, database) scale independently; new categories and channels can be added without redesign.

Expected Outcomes

- Reduced time spent on manual triage.
- Higher first-time routing accuracy.
- Better SLA compliance for high-priority tickets.
